insertion 1

insertion. An *insertion* is a vertical list containing material to be inserted into a page when TEX has finished building that page. Examples of such insertions are footnotes and figures. The plain TEX commands for creating insertions are \footnote, \topinsert, \midinsert, and \pageinsert, as well as the primitive \insert command itself (pp. '\footnote'-'endofinsert'). TEX's mechanism for handling insertions is rather complicated; see pages 122–125 of *The TEXbook* for the details.

 $^{^1}$ TeX itself doesn't insert the material—it just makes the material available to the output routine, which is then responsible for transferring it to the composed page. The only immediate effect of the \insert command (p. '\insert') is to change TeX's page break calculations so that it will leave room on the page for the inserted material. Later, when TeX actually breaks the page, it divides the inserted material into two groups: the material that fits on the current page and the material that doesn't. The material that fits on the page is placed into box registers, one per insertion, and the material that doesn't fit is carried over to the next page. This procedure allows TeX to do such things as distributing parts of a long footnote over several consecutive pages.
