1

output routine. When TEX has accumulated at least enough material to fill up a page, it chooses a breakpoint and places the material before the breakpoint in \box255. It then calls the current *output routine*, which processes the material and eventually sends it to the .dvi file. The output routine can perform further processing, such as inserting headers, footers, and footnotes. Plain TEX provides a default output routine that inserts a centered page number at the bottom of each page. By providing a different output routine you can achieve such effects as double-column output. You can think of the output routine as having a single responsibility: disposing of the material in \box255 one way or another.

The current output routine is defined by the value of \output (p. '\output'), which is a list of tokens. When TEX is ready to produce a page, it just expands the token list.

You can make some simple changes to the actions of the plain T_FX output routine without actually modifying it. For example, by assigning a list of tokens to \headline or \footline (p. '\footline') you can have T_FX produce a different header or footer than it ordinarily would.

The output routine is also responsible for collecting any insertions; combining those insertions and any "decorations" such as headers and footers with the main contents of the page and packaging all of this material in a box; and eventually sending that box to the .dvi file with the \shipout command (p. '\shipout'). Although this is what an output routine most often does, a special-purpose output routine might behave differently.
